Sir:

CLAIM FOR PRIORITY

Under the provisions of 35 U.S.C. § 119, Applicants hereby claim the benefit of the filing date of European Patent Application No. 02078651.3, filed September 6, 2002, for the above-identified U.S. patent application.

In support of this claim for priority, enclosed is one certified copy of the priority application.

Respectfully submitted,

FINNEGAN, HENDERSON, FARABOW,
GARRETT & DUNNER, L.L.P.

The present invention concerns apparatuses for pressing of edible articles comprising a holding device with at least one cooling channel and carrying a number of independently suspended, cooled plungers which is pressed into the mass. Many types of mass may apply as long as the mass is capable of reaching a deformable state before being pressed into shape. Chocolate mass, whether it is in a highly liquid state, a thick paste-like, viscous state or in a powder form may for example apply. The chocolate mass may have a content of genuine cocoa butter or simply be a so-called chocolate-like mass by which the butter is substituted with other kinds of fats or oils such as palm-kernel oils. Decisive is, that the particular mass in question is deformable by the pressing action of cold plungers.

The mass may be deposited in an underlying mould cavity or directly as lumps upon a conveyor belt or supporting surface before the pressing operation. The intention could also be to press or stamp a covering chocolate layer deposited upon a previously made edible article, such as a chocolate article. The covering layer to be pressed could for example be a bottom covering layer deposited upon a centre mass deposited into the inner cavity of a pre-made chocolate shell.

An inner chocolate layer on pre-made articles could also be made, for example by depositing tempered chocolate-like mass in an already made shell, optionally shaking the moulds, and then immersing cold plungers into the deposited mass for making shells with predetermined and even thickness. The first pre-made shell could be of one chocolate type such as ordinary milk chocolate and the inner chocolate layer made subsequently could be of another chocolate type, such as a white chocolate type.

When for example shells are to be made, an apparatus comprises a plate-like holding device carrying a number of cooled plungers to be immersed into underlying mould cavities in a mould plate. In each mould cavity is deposited liquid chocolate, and by lowering the holding device, the plungers are simultaneously immersed into the chocolate in the different mould cavities. By the pressing action of the plungers, the chocolate mass is pressed into shells having the desired shape. Due to the cooling of the plungers a forced solidification of the influenced chocolate mass is achieved in contact therewith. The chocolate mass then contracts slightly and re-

leases the pressing surfaces of the plungers which may be lifted up and free therefrom within seconds.

Generally, chocolate masses are suspensions of non-fat particles such as sugar,
5 milk powders and cocoa solids mixed up with a liquid fat constituent. Often, the fat phase comprises genuine cocoa butter of until around 30%, but may comprise substitutes as well. Such substitutes can be in the form of other types of fat-containing oils. Chocolate types where the cocoa butter has been replaced wholly or partly by other fats are often named commercially as compound chocolate, in which the
10 cocoa butter has been replaced by palm-kernel oil. Mass made of 100% fat in the form of cocoa butter or the like as compound is also possible.

However, for the chocolate-like masses it is decisive, that whether the fat phase constitutes of genuine cocoa butter or substitutes thereof, the fat phase is capable of
15 crystallizing into stable crystal types, such as the β -crystals developing in genuine cocoa butter when the mass solidifies.

Before being supplied in liquid state to the apparatus, the chocolate is typically being treated for providing stable beta-V crystals at solidification. The treatment could be a
20 tempering process by which the mass is generally brought to around 40-50°C, whereafter it is being cooled to around 25-34°C, so that crystallisation is initiated. Then the mass is reheated around 0,5-2,0°C for re-melting most of the in-stable crystals in the mass, however preserving a content of stable β V-crystals, which melts at a higher temperature than the in-stable crystals. The stable crystals are
25 preserved in the mass ready for depositing in an amount of typically 0,01% - 5%, preferably in an amount of 0,1% - 2%. Before being supplied the chocolate could also be treated by other processes such as cooling the chocolate to around 30-34°C, then seeding it with already made powder having a content of desirable beta V crystals for ensuring the solidification into proper crystals.

30 After the shells made have solidified, they may be filled with a centre mass of a creamy or liquid food material, which differs from that of the shell material. The centre mass could be an alcohol containing mass, a sugar containing mass or a creamy fondant mass, simply any of the centre masses known to the chocolate industry.
35 Finally, a chocolate covering layer may be deposited for closing the centre mass off,

thereby creating a complete article. The articles could have any shape, size and configuration and could typically be "pralines", tablets, or slabs such as for example the well-known quadrangular slabs with all kind of centre masses.

- 5 Advantageously, the chocolate covering layers can be pressed with an apparatus according to the invention, however, also chocolate covering layers deposited upon other types of edible articles may advantageously be pressed with the inventive apparatus. Edible articles such as bars, biscuits or bakery articles are generally excellent to provide with a chocolate covering layer being pressed by the inventive apparatus.

10

- If a bottom covering layer is not created on a pre-made shell, the articles made by the apparatus could typically be figures or eggs or egg-like articles, which are created by joining together two chocolate shells with each other. Both shell halves may 15 be made with the inventive apparatus, and a centre mass may be deposited before the halves are being joined. Instead of a centre mass the cavity between the joined shells could simply contain some kind of surprise, such as a small plastic container comprising kids toys inside the well-known "Surprise" eggs.

20

- WO 98/52425 (KMB, Knobel) discloses an apparatus having numerous plungers permanently fixed to a carrier or holding plate. The carrier plate as well as the plungers comprise major inner channels through which cooling liquid is forced to flow for achieving the necessary cooling of the plungers. Such construction may be used when relatively large articles such as Easter eggs or surprise eggs are to be 25 made. However, the inner channels of the plungers makes it expensive to manufacture. When smaller articles are to be produced, the smaller plungers with inner channels becomes difficult, very expensive and if not impossible to make. Furthermore, the inner channels of such small or slim plungers becomes insufficient for providing the necessary cooling to the plungers and then to the chocolate being pressed. The plungers are fixed to the plate-like holding device and is impossible to 30 replace with other plungers having different configuration, shape or size.

35

- WO 98/52425 (KMB, Knobel) furthermore discloses, that the plungers are arranged with substantial mutual distance at the holding device without consideration to an optimal utilization of the fixed surface area of the mould plates. The result is a pro-

duction capacity being considerably lower than desired. For the manufacturer of the chocolate articles it is of outmost importance for his economy to press as many articles as possible each time the holding device makes a pressing operation.

- 5 EP 0923876 A discloses an apparatus of the introductory type and by which the independently suspended plungers are made in one solid piece with the same cross-sectional shape in all of their length. The upper part of each plunger comprises sliding surfaces and is arranged vertically movable in a hole in the holding device. Sliding surfaces of the upper part is then supported by opposite sliding surfaces of the hole in the holding device.

10 The sliding surfaces transmits cooling from the holding device and to the pressing surfaces for cooling the warmer chocolate when being pressed. Each plunger may be further supported by an upper slim slide guidance.

- 15 However, plungers with such length as disclosed in the EP-publication and in practice being between 50-100 mm necessary for obtaining proper support by the opposite sliding surfaces of the holding device, is very expensive to manufacture. Complex shapes of the articles available on today's market requires that the plungers are
- 20 made with complex cross-sectional shapes as well.

- 25 The lower part of the plungers having the pressing surfaces is created with the exact shape for making the inside or contour of the pressed chocolate articles. As disclosed in the EP-publication the same exact cross-sectional shape is preserved all the way up through the upper plunger part and to the top thereof incorporating the sliding surfaces of the plunger.

- 30 The disclosed configuration requires the best and most accurate technologies within the art of tool-making with the consequence, that the manufacturing expenses of the plungers becomes excessively high. The expenses of making the corresponding openings with the opposite sliding surfaces in the holding device are high as well. The sliding surfaces of the openings as well as the sliding surfaces of the plungers are made with very fine tolerances for obtaining proper and un-problematic function during long-time pressing of articles.

In total, the manufacturing expenses of making the plungers and the corresponding openings of the holding device becomes a major part of the apparatus, which typically carries between 50 and 200 plungers depending on the size of the articles to be pressed.

5

As the expenses of making the plungers and the corresponding holes with the opposite supporting gliding surfaces in the holding device constitutes a substantial part of the total expenses of manufacturing the apparatus, it becomes important to reduce the expenses of making the plungers and the supporting holes in the holding

10

device.

15

The holding device and the plungers are furthermore only adapted to make articles with one specific shape and configuration as determined by the configuration of the pressing surfaces and cross-sectional shape of the plungers being preserved all the way to the top working in the holding device. Articles with other configurations and shapes are impossible to make with the same apparatus. Every time a differently configured article is to be produced with the same apparatus another holding device with differently shaped openings with slide surfaces and a correspondingly shaped new set of plungers must be produced.

20

Articles with slim or simply width-varying cross-sectional shapes, that deviates from purely quadrangular shapes have proven to be impossible to make as the sealing of the sliding surfaces seemed practically impossible to obtain and the expenses of manufacturing sealings as well as the sliding holes in the holding device as well as the required outer shape of the plungers were out of reach.

25

30

For the manufacturer of the chocolate articles it is furthermore crucial to his business to achieve as high capacity as possible of the apparatus, so that as many articles as possible are pressed within a given time period. Consequently, the apparatus must produce as many articles as possible per pressing operation, i.e. each time the holding device is lowered against the underlying mould or conveyor belt.

35

When the articles are pressed in mould cavities, the available area for pressing the articles is determined by the size of a standard mould, which typically has a width of 275 mm and a length of 625 mm. Within this area as many moulds and plungers as

possible must be arranged for reaching the highest pressing capacity of the apparatus. A decisive factor for reaching as high production capacity of the apparatus as possible is then the compactness of the arrangement of the plungers at the holding device.

5

A problem to solve is to provide a solution by which it is possible to make articles with slim or simply width-varying cross-sectional shapes. Shapes by which one side is longer than the other side and deviates from simple quadrangular shapes or pure circular shapes.

10

Another problem to solve is to provide an apparatus of the introductory art which is capable of producing as many articles as possible per pressing operation and which apparatus yet is considerably simpler and less cost expensive to produce than the prior known ones.

15

A further problem to solve is to provide an apparatus of the introductory art which is adapted for making optionally, differently shaped products.

The apparatus according to the present invention is characterized in, that each
20 plunger comprises a lower part with non-circular cross-section and at least two upper parts with circular cross-sections, and that the parts are separate parts, which are joined together.

Hereby is obtained, that the plungers are arranged closely to each others at the
25 holding device and yet is sufficient cooling of the lower plunger parts secured through the at least two upper plunger parts per plunger having circular cross-sections. The solution is advantageous for complex shapes or configurations of the cross-sections of the plungers and articles to be pressed, i.e. typically shapes that deviates from purely quadrangular cross-sections. The shape of the lower plunger

30 parts are made separately without taking care of the holes in the holding device. The number of upper plunger parts are then chosen with a view of obtaining the appropriate cooling through the sliding surfaces thereof. If for example three upper plungers are chosen three holes are simply drilled for each plunger into the holding device and the upper plunger parts with circular cross-sections are arranged in the holes
35 after being joined to the lower plunger parts.

The circular cross-section of the upper plunger parts requires only gaskets with a standard circular shape so that the sliding surfaces may easily be tightened against the outside regardless of the shape of the articles to be pressed.

- 5 If at least the major part of the circular cross-sections of the upper plunger parts are arranged within the outer periphery of the cross-sections of the lower plunger parts, the plungers may be arranged especially close to each others. By major part is meant, that typically up to 10% of the cross-sectional areas of the upper plunger
- 10 parts are allowed to extend outside the periphery of the cross-sections of the lower plunger parts. Also may a rim or ring at the joint between the upper and lower plunger parts extend slightly such as 1-5 mm outside the periphery of the lower plunger parts. Decisive is, that the possible extension of the upper plunger parts or parts for joining them with the lower plunger parts does nor interfere with the close arrangement of the individual plungers to each others.
- 15

The lower plunger parts may then be arranged closely to each other at the holding device, so that a tremendous high pressing capacity is achieved for the apparatus.

- 20 The inventive solution is especially advantageous for slim or lengthy cross-sectional shapes as the at least two upper plunger parts may be arranged very closely to each others, so that the circular cross-sections secures a high total cooling area between the plungers and the holding device through the sliding surfaces for each plunger. The limit for the close arrangement is the necessary width in the holding device for cooling channels between the upper plunger parts and for material thickness in the mould plate between individual mould cavities when articles are to be pressed in moulds. These criteria has been proven to be satisfied when the distance between the individual plungers are as low as 4-5 mm.
- 25
- 30 Furthermore is obtained, that the holding device and the movable, upper plunger parts arranged in the openings with the sliding surfaces are made in the simplest possible manner as a separate unit independent of the required shape and geometry of the articles to be made. The lower plunger parts comprising the complex geometry of the pressing surfaces are also made as separate units, which are then

joined to the upper plunger parts in the holding device when the articles having the particular shape are to be produced.

- 5 The upper plunger parts as well as the supporting openings in the holding device all have circular cross-sections and are thereby made by basic, simple drilling and milling operations. Consequently it have become simple, fast, and cheap to make the upper plunger parts and especially the supporting holes. The expenses are typically reduced between 50 and 90%. Only the lower plunger parts are made with the required non-circular geometry of the articles to be pressed.
- 10 For plungers having complex geometries, i.e. cross-sections other than circular or having relatively slim or small cross-sections it is then avoided, that the pressing surfaces of the plungers functions as sliding surfaces supported by opposite sliding surfaces of the holding device. Every part of the surfaces of the plungers can be moving outside contact with the holding device, yet is obtained an efficient heat transport and cooling of the plungers through the upper circular plunger parts.
- 15 Another advantage is, that the different lower plunger parts fixed to the same holding may have different configuration, so that differently shaped chocolate articles may be pressed with the same holding device. The mutual arrangement or pattern of the differently shaped articles pressed in the same pressing stroke may be transferred directly into a sales box. Cumbersome handling and sorting of differently shaped articles are thereby avoided.
- 20 However, when differently shaped articles are to be produced, this can be done in the one and same production line. Differently shaped lower plunger parts are simply joined with the upper plunger parts of the same holding device. The underlying moulds then comprises differently shaped cavities arranged under the appropriate lower plunger parts. Several differently shaped articles are then made in the same moulding operation and the need for further moulding lines are avoided. The differently shaped lower plunger parts may be arranged in a mutual pattern, which is desirable to be transferred directly into a box, such as a gift box when the articles are to be packed.
- 25
- 30

- The utility of the holding device as a separate unit with the upper plunger parts makes it possible to provide it in different standard configurations onto which differently shaped lower plunger parts may be fixed for pressing differently sized articles.
- One holding device may comprise 40 upper plunger parts having a diameter of 5 mm being evenly distributed over the prefixed holding plate of the device. The lower plunger parts fixed to that holding device could for example have a configuration for making shells for slabs or tablets.
- Another holding device having the same size of the holding plate may comprise 60 evenly distributed upper plunger parts having a diameter of 35 mm. The lower plunger parts to be fixed to that holding device could for example have the configuration adapted to press a chocolate covering layer of a biscuit.
- Yet another holding device still having the same size of the holding plate may comprise 80 evenly distributed upper plunger parts having a diameter of 25 mm. The configuration of the lower plunger parts suitable for this configuration of the holding device may for example be suitable for pressing shells for "Pralines" or bottom coverings thereof.
- The apparatus may comprise a closure plate having openings through which the lower plunger parts extends, and which is movably suspended below the holding device. When lowering the holding device the closure plate comes to rest upon the upper surface of the mould plate. Thereby, a completely tight closure of the mould cavities is achieved before the holding plate and consequently the lower plunger parts are lowered further and under pressure causes the chocolate mass to completely fill out the moulding cavities. Subsequently cutting of the upper rims of the articles are then unnecessary and dirtying of the moulds and production facilities with cut-off particles of chocolate is then avoided.
- The invention is explained further below by reference to preferred embodiments as well as the drawing, in which
- fig. 1 is a schematical, perspective view of part of a production plant according to the invention,

fig. 2 is a detailed view of part of the conveyor and mould plates of the plant disclosed in figure 1.

- 5 fig. 3 is a schematical view of a first holding device, seen from below without any lower plunger parts,

fig. 4 is a schematical section of a part of the holding device, for clarity disclosing only two plungers of the multiple 80 plungers as well as disclosing only two underlying mould cavities of the multiple 80 mould cavities in each mould plate with deposited chocolate in.

10 ited chocolate in,

fig. 5 is the same disclosed in a lower position by which the closure plate of the holding device has come to rest upon the mould plate.

- 15 fig. 6 is the same disclosed in the lowermost position of the holding device and the plungers at which the chocolate is pressed to complete filling out of the enclosed cavity,

fig. 10 is a schematic section of another plunger with a yet different shape for
pressing articles with a "waist"-like shape.

Fig. 10 is a schematic section of another plunger with a yet different shape for
pressing articles with a "waist"-like shape.

The apparatus disclosed in figure 1 constitutes part of a major plant for manufacturing of chocolate articles. The apparatus comprises a shell moulding section 1, a

35 tions is optional within the inventive idea as only one section is necessary for per-

forming a pressing operation such as a shell pressing or a bottom pressing. Neither is the inventive idea limited to any particular configuration of the articles such as shells as long as the mass simply is capable of being pressed out to the required geometry of the desired article. Other examples of articles are tables or bars and 5 pressing of chocolate covering layers upon pre-made articles such as upon filled shells or upon pre-made biscuits.

A continuously moving conveyor 4 extends through the stations 1, 2 and 3 and carries a great number of juxtaposed mould plates 5. For sake of simplicity is only disclosed the part of the conveyor 4 running through the depicted stations 1, 2 and 3. 10 Subsequently to the bottom covering pressing station 3 is normally arranged a cooling tunnel and a wrapping section. Both the disclosed shell moulding section 1 and the bottom covering pressing section 3 comprise the inventive idea.

15 The schematically disclosed housing 6 comprises some kind of depositor means, which deposit the edible mass and as in the disclosed example ready tempered chocolate mass into the individual mould cavities 7 of each mould plate 5. Each mould plate 5 comprises typically between 100 and 120 mould cavities as disclosed in figure 2 when the articles to be pressed have the disclosed "slim" bar-like configuration. 20 Each individual mould plate 5 is then carried on by the conveyor 4 and passes over a shaking table 8, which distributes the deposited chocolate evenly within the individual mould cavities 7.

Then the mould plates 5 enters the shell moulding or pressing housing 9, within 25 which the deposited chocolate is pressed by the action of the plungers into shape of the desired articles. In the moulding housing 9 is arranged a schematically disclosed holding device 10. The holding device 10 is arranged with known means such as columns and slides, a motor for creating the movement and related control panels and software for controlling the up- and down movement of the holding device 10 30 each time it is in engagement with a mould plate 5 and articles are pressed in the mould cavities 7.

As disclosed in figures 3-6 the holding device 10 comprises at least one channel 11 35 for circulation of a cooling liquid and carries a plurality of independently suspended plungers 12. Each plunger 12 has a lower part 13 with pressing surfaces 14 to be

pressed into contact with the mass 15 in the mould cavity 7. Each plunger 12 also comprises at least two upper parts 16 with sliding surfaces 17 supported by opposite sliding surfaces 18 of openings 19 in the holding device 10.

- 5 The upper plunger parts 16 has a circular cross-section and fits into the openings 19, which also features a circular cross-section. In figure 2 the holding device 10 is disclosed from below without the lower plunger parts 13, so that the circular cross-sections of the upper plunger parts 16 easily can be seen.
- 10 As disclosed in figures 3-6 the lower plunger parts 13 are each joined with two upper plunger parts 16, for example by simple screw joints 20, so that the lower parts 13 fast and easily may be changed with parts having different configurations.
- 15 The upper plunger parts 16 and the supporting openings 19 of the holding device 10 are simple and cheap to make by basic drilling and milling operations. Only the lower plunger parts 13 are made with the required non-circular geometry of the articles to be pressed. The expenses of making the holding devices are typically reduced with 50-90% in comparison with the prior art. Each holding device may furthermore be fitted with lower plunger parts 13 having essentially any configuration and shape so that a holding device with plungers fitted are not limited to the pressing of only one specific article with particular shape and configuration as by the prior art.
- 20
- 25 The configuration is useful when odd shaped of the articles are to be made. In the example of figures 3-6 is disclosed a relatively long, slim cross-section of the lower plunger part 13, which is to be used for obtaining the desired geometry of the articles 36 to be pressed, i.e. figure 8. By joining the lower plunger parts with such configurations with at least two upper plunger parts 16 having smaller circular cross-sections instead of joining them with only one upper plunger parts, the plungers may be arranged closely to each other at the holding device 10 and yet is sufficient cooling of the lower plunger parts 13 achieved through the multiple upper plunger parts 16. The closer arrangement of the lower plunger parts 13 to each other obtains a high number of mould cavities in each mould plate and consequently an optimal high number of articles to be pressed in each pressing stroke.
- 30
- 35

The apparatus may advantageously be fitted with a closure plate 21 having openings 22 through which the lower plunger parts 13 extends, and which is movably suspended below the holding device 10.

- 5 Before a pressing operation the holding device 10 is brought in line with the next underlying mould plate 5, so that each plunger 12 is exactly above an underlying mould cavity 7 in the particular mould plate 5. During the pressing operation the conveyor 4 is stopped or the holding device is forced to run synchronously with the same speed as that of the conveyor 4. In the secondly mentioned option the holding device is retracted to its initial starting position after completion of a pressing operation and so that a new may be initiated.
- 10

Before the actual pressing operation the holding device 10 is lowered to such extend, that the closure plate 21 has come to engagement with the upper surface 23 of the underlying mould plate 5, so that safe enclosure of all of the pressing cavities is obtained as depicted in figure 5.

- 15
- 20
- 25
- 30
- The closure plate 21 is typically suspended by a non-disclosed spring means to the holding device, so that by the further lowering of the holding device the closure plate is kept pressed on to the upper surface 23 of the mould plate 5. The multiple plungers 12 of the holding device then moves further on into engagement with the chocolate mass 15 by the continuing lowering of the holding device 10 as depicted schematically in figure 5 by disclosing only two plungers 12. The mass is pressed out into complete filling out of the enclosed cavity as disclosed in figure 6, so that the full geometry of the desired articles 24 is obtained. The upper plunger parts 16 may be acting against a springload created by springmeans or pressurized air between the plunger part 16 and the holding device 10, for example transferred via a slim guide pin 25. Gaskets 26 may be arranged for supporting the periphery of the plunger part 16 and closing off the gap between the sliding surfaces 17, 18.

After that the pressing of the articles 24 is completed, the holding device 10 is retracted to its upper position being ready for a new pressing to follow.

- 35
- During the pressing, circulation of cooling liquid through the channels 11 of the holding device is controlled by the schematically depicted unit 26 connected with the

P 463 EP00 "Apparatus for pressing edible articles"

14

- channels via hoses 27. The unit 26 comprises a cooling device for keeping a constant temperature of the circulating liquid or for keeping a constant temperature at a surface, such as typically at the pressing surfaces 14 of the lower plunger parts 13. The temperature may advantageously be as low as between +5 and -25 degrees Celsius, however decisive is, that the temperature of the pressing surfaces is kept below the solidification temperature of the particular mass being pressed. The pressing surfaces are typically of high gloss and are free of any lubricant.
- 5 An air drying device 28 is connected to the housing 9 via a hose 29 and is adapted to blow or circulate dry air through the housing 9. The humidity may be lowered to such extent, that no condensation is created on the pressing surfaces whatever the temperature of the pressing surfaces may be. However, for the pressing of some masses it may also be desirable, that the dewpoint temperature of the air is slightly above the surface temperature of the pressing surfaces. The humidity is simply 10 regulated in accordance with the actual requirement for the articles to be pressed.
- 15 By the particular embodiment the mould plates 5 with the ready pressed shells or tablets 24 are moved on through the centre filling section 2, at which an optional centre mass such as cream or a crunchy mass 30 is deposited into the inner cavity 20 of each tablet 24. Advantageously, the mould plates 5 passes over a shaking table 31 for obtaining secure spreading of the centre mass 30 in the tablet or shell 24.
- 25 Thereafter, the mould plates 5 passes into a station 32 for depositing a chocolate covering layer 33 on to the articles 24 with centre mass 30 for closing of the centre mass. Thereafter, the mould plates 5 moves on into the final bottom covering pressing station 3. The station 3 is in principle identical to the station 1 apart from that the lower plunger parts 13 have been replaced by lower plunger parts 34 with flat pressing surfaces 35 for pressing of the covering 33.
- 30 Then, the station 3 comprises a holding device 10 functioning in exactly the same manner as that of station 1. As depicted in figure 1 a unit 26 may also be arranged for controlling the temperature of the cooling liquid and a drying unit 28 may be arranged for controlling the humidity of the housing 9 of the station 3. The ready made chocolate article 36 is disclosed in figure 8.

35

P 463 EP00 "Apparatus for pressing edible articles"

15

Another example of a plunger 37 according to the inventive idea is disclosed schematically in figure 9. The plungers 37 each comprises four upper parts 38 with circular cross-sections and a lower part 39 with non-circular cross-section. The lower part 39 with non-circular cross-section is elongated, slim-like and is adapted for the 5 pressing of chocolate shells for banana-like articles.

In figure 10 is disclosed another example of a plunger 40 having a lower plunger part 42 with a shape having varying width and as well as a waist-like configuration. Each lower plunger part 42 is joined with four upper plunger parts 41 having circular 10 cross-sections, that secures the transferring of the necessary cooling from the holding device to the lower plunger part 42.

15

CLAIMS

1. Apparatus for pressing edible articles (24, 36) comprising a holding device (10) with at least one channel (11) for circulation of cooling liquid and carrying independently suspended plungers (12) having lower parts (13; 34) with pressing surfaces (14; 35) to be pressed into contact with the chocolate mass (15) as well as having upper parts (16) with sliding surfaces (17) supported by opposite sliding surfaces (18) of openings (19) in the holding device (10),
5
10 characterized in,
that each plunger (12) comprises a lower part (13; 34) with non-circular cross-section and at least two upper parts (16) with circular cross-sections, and that the parts (13; 34, 16) are separate parts, which are joined together.
15
2. Apparatus according to claim 1, characterised in, that the upper and lower parts (13, 16) are joined to each other by screw joints (20).
3. Apparatus according to claim 1, characterised in, that at least the major part of
20
the circular cross-sections of the upper plunger parts (16) are arranged within the outer periphery of the cross-sections of the lower plunger parts (13).
4. Apparatus according to claim 1, characterised in, that the diameter of the upper
25
parts (16) with sliding surfaces (17) are equal to or less than the greatest width of the lower plunger parts (16).
5. Apparatus according to claim 1, characterised in, that at least one of the non-circular cross-sections of the lower plunger parts are different from the others.
30
6. Apparatus according to claim 1, characterised in, that the apparatus comprises a closure plate (21) having openings (22) through which the lower plunger parts (13) extends, and which is movably suspended below the holding device (10).
35
7. Apparatus according to claim 1, characterised in, that the apparatus is adapted to keep the temperature of the pressing surfaces (14) below the solidification tempera-

ture of the tempered chocolate mass during the pressing thereof by circulation of cooling liquid through the channels (11) of the holding device (10).

8. Apparatus according to claim 1, characterised in, that the upper and lower

5 plunger parts (16, 13) are essentially free from inner channels for flow of cooling liquid.

9. Apparatus according to claim 1, characterised in, that the mass is pressed in underlying mould cavities (7).

10

15

ABSTRACT

"Apparatus for making chocolate articles"

- 5 Apparatus for pressing articles (24) of chocolate mass comprising a holding device (10) with at least one channel (11) for circulation of cooling liquid and carrying independently suspended plungers (12). The plungers have a lower part (13) with pressing surfaces (14) and non-circular cross-section to be pressed into contact with the chocolate mass (15) as well as at least two upper parts (16) with circular cross-section and sliding surfaces (17) supported by opposite sliding surfaces (18) of openings (19) in the holding device. The necessary cooling is then obtained in the plungers and yet may the individual plungers be arranged closely at the holding device, so that a high pressing capacity is achieved. The holding device (10) with the plungers (12) are simple and fast to make and the lower plunger parts (13) may be changed with others having the desired shape of the articles to be pressed without changing the hole holding device (10). Plungers having different shapes may also be arranged at the same holding device.
